Result 1 (saved equality). [Bound operator study, fixed operator selection]
Let n be a natural number. Assume $n = n$ (`h`). Let q = retain equation(n, h). Then

$$n = n.$$

Result 2 (implication application). [Bound operator study, implication authored as a quantified condition]
Let P and Q be conditions. Assume P implies Q (`h`). Assume P (`p`). Let $q = h(p)$. Then

$$Q.$$

Result 3 (saved quantified annotation). [Bound operator study, fixed operator inside a binder domain]
Let n be a natural number. Assume (for every $v : \mathbb{R}^{n+n},\ v = v$) (`h`). Let q = keep quantified(n, h). Then

$$\left(\text{for every } v : \mathbb{R}^{n+n},\ v = v\right).$$

Grouping checks. The operator and named negation forms have the same rendering:

$$\text{not } (P \text{ implies } Q).$$

A right-nested named sum preserves its parentheses:

$$n + (n + n).$$

Isolated operator/binding composition. LLM-assisted statements and proofs (gpt-6, 2026-11-07); see PROVENANCE.md. Main Clean does not enable these operator declarations. Rendering is not a proof certificate.
